Lab Task 1: Online Café Food Ordering System

Scenario

You are developing a simple **Online Café Food Ordering System** for a café called “**Campus Café.**”

The café wants a webpage where students can select food items, provide their information, and place an order. The webpage should use **HTML for structure, CSS for design, and JavaScript for validation and calculation.**

Task Requirements

Create a webpage named **index.html** with the following features.

1. Customer Information — HTML

Create a form containing:

- Full Name — Text field
- Email — Email field
- Phone Number — Text field
- Student ID — Text field
- Gender — Radio buttons
 - Male
 - Female
- Department — Dropdown
 - CSE
 - EEE
 - BBA
 - English
 - Other

2. Food Selection — HTML

Add the following food items with checkboxes:

Food Item	Price
Burger	\$5
Pizza	\$8
Sandwich	\$4
French Fries	\$3
Coffee	\$2
Cold Drink	\$2

The customer should be able to select **multiple items**.

Also include:

- Quantity field
- Special Instructions — Textarea

3. CSS Design

Use an external stylesheet named **style.css**.

The webpage should:

- Have a centered form container.
- Use a suitable background color/image.
- Style all input fields.
- Style buttons with hover effects.
- Use proper spacing and alignment.
- Make the food items visually attractive.
- Highlight input fields when they receive focus.
- Display validation errors in **red**.
- Make the page responsive for smaller screens.

4. JavaScript Validation

Create a separate file named **script.js**.

When the user clicks **Place Order**, JavaScript should validate:

1. Name cannot be empty.
2. Email must contain a valid email format.
3. Phone number cannot be empty.
4. Student ID cannot be empty.
5. Gender must be selected.
6. Department must be selected.
7. At least **one food item** must be selected.
8. Quantity must be greater than 0.
9. Special instructions are optional.

Display appropriate error messages below the corresponding fields.

5. Bill Calculation

After successful validation, JavaScript should calculate:

Total = Food Price × Quantity

For example:

Burger = \$5

Coffee = \$2

Quantity = 2

Total = (\$5 + \$2) × 2 = **\$14**

Display the result dynamically on the webpage.

The output should contain:

Customer Name: John

Student ID: 23-12345-1

Department: CSE

Selected Items:

Burger - \$5

Coffee - \$2

Quantity: 2

Total Bill: \$14

6. Order Confirmation

After successful order submission, display:

“Order placed successfully!”

Also display the customer's name and total bill.

Do **not** use `alert()` for the final result. Display the result inside the webpage using JavaScript and DOM manipulation.

must submit:

CampusCafe/

- |
- |— index.html
- |— style.css
- |— script.js

Follow the submit instructions for git.
